

Antiperspirant and Breast Cancer: Linked?

The information below is taken from the FDA newsletter that I receive: "FDA is aware of concerns that antiperspirant use -- in conjunction with underarm shaving -- may be associated with increased risk of developing breast cancer. FDA continues to search scientific literature for studies examining this possible adverse drug effect. Unfortunately, there are many publications that discuss the issue but very few studies in which data have been collected and analyzed. Overall, the studies that contain data are inconclusive in determining whether antiperspirants, in any way, contribute to the development of breast cancer. FDA hopes that definitive studies exploring breast cancer incidence and antiperspirant use will be conducted in the near future." The issue is the aluminum found in antiperspirants. Given this fact, numerous companies in the beauty industry are shifting away from adding aluminum and other potentially harmful ingredients to their products. Why wait for solid proof that aluminum is causing breast cancer - especially as there are alternatives. Visit your health store, pharmacy or even quality supermarket. There you will find aluminum free deodorants.
